Avoiding Dangerous Climate Change – 2\textsuperscript{nd} Keynote Address

R K Pachauri
Director General TERI and Chairman, IPCC
A Scientific Symposium on Stabilization of Greenhouse Gases - Exeter, UK
1\textsuperscript{st} February, 2005
Some Overriding Issues

- Defining “dangerous” is a value judgment
- But some cardinal principles apply
  - Universal human rights
  - Needs of future generations (sustainable development)
- Science can provide the basis
  - Impacts and damage
  - Socio-economic dimensions
The Threshold Approach

- Setting an explicit threshold as dangerous – how valid?
- Reaching the threshold depends on
  - Initial conditions
  - Marginal impacts and damage
  - Costs or valuation of impacts
  - Irreversibility and adaptation
  - Mitigation options
Some Issues of Global Concern

- Dangerous for whom -
  - equity dimensions
- Dangerous by when –
  - inertia in the system
  - inter-generational issues
  - plausible adaptation scenarios
  - plausible mitigation scenarios
- Defining the action required
Some Practical Questions

- Can a temperature target capture the limits of what is dangerous?
- Do we have the scientific rationale for setting this target?
- Can a global target represent dangers at the local level?
- How do we determine a concentration level for GHGs?
- What is the trajectory to achieve stabilization?
Some Initial Conditions – Taking Stock

- Increase in global mean surface temperature by over 0.6°C (*highly likely*)
- Decrease in Artic sea ice extent by 10-15% and in thickness by 40% (*likely*)
- Decrease in snow cover area by 10% since observation started in 1960 (*very likely*)
- Coral reef bleaching
- 1990 – the warmest decade of the millennium (*likely*)

Dangerous for Whom? Some Future Estimates

- Sea level rise and agricultural changes due to climate change are estimated to result in 150 million environmental refugees by 2050.

- Total flood zone refugees in India alone could be anywhere between 20 million and 60 million, with 30 million taken here as a conservative working figure.

- 17% of Bangladesh could be permanently lost to sea level rise coupled with land subsidence. Even with engineering works an estimated 15 million would be displaced.

- Egypt would lose between 12 -15 % of its arable land.

- 50 million people globally may be displaced due to climate change-induced famine.

Dangerous for Whom? Extreme Events

- The number of disasters of hydro-meteorological origin have increased significantly
- Increase in precipitation in the mountains along with melting of glaciers - increased incidence of floods, mudslides and avalanches
- Recurring incidence of floods and droughts is already apparent (temperate Asia)
- Large areas with high population densities are susceptible to floods, droughts and cyclones in Bangladesh and India. Vulnerability to extreme weather events are expected to increase in these areas

Source: TAR, WGII
Extreme events are a major source of climate-related impacts. E.g., heavy losses of human life, property damage, and other environmental damages were recorded during the El Niño event of 1997-1998. The impacts of climatic extremes and variability are a major concern. Preliminary indications suggest that some social and economic systems have been affected by recent increases in floods and droughts, with increases in economic losses for catastrophic weather events.

The number of weather-related catastrophic events has risen three times faster than the number of non-weather-related events, despite enhanced disaster preparedness. Part of this upward trend in weather-related losses over the past 50 years is linked to socio-economic factors (population growth, increased wealth, urbanization in vulnerable areas), and part is linked to regional climatic factors (e.g., changes in precipitation, flooding events).

Most insured damages were in the north
Most people were affected in the South

**Economic and Insured losses related to weather extremes**

**Decade Comparison (losses in US$ billion, 1999 values)**

Can We Adapt to Irreversible Changes?

Coral Reef Bleaching

- Increased frequency in the 20th century, especially during El Niño events
- The worldwide increase in coral bleaching in 1997-1998 was coincident with high water temperatures associated with El Niño

Frequency and severity of drought

- Increased summer drying and associated incidence of drought in a few areas. In parts of Asia and Africa, the frequency and intensity of droughts have been observed to increase in recent decades.

Source: IPCC TAR
Can We Adapt to Irreversible Changes?

Duration of ice cover of rivers and lakes
- Decreased by about 2 weeks over the 20th century in mid- and high latitudes of the Northern Hemisphere

Arctic sea-ice extent and thickness
- Thinned by 40% in recent decades in late summer to early autumn and decreased in extent by 10-15% since the 1950s in spring and summer.

Non-polar glaciers
- Widespread retreat during the 20th century.

Source: IPCC TAR
How Likely Are Possible Singular Events?

- Breakdown of the thermohaline circulation
- Disintegration of the West Antarctic ice sheet
- Shift in mean climate towards an El Nino like state
- Runaway carbon dynamics - reduced sink capacity, release of methane from hydrates, carbon from permafrost
- Rearrangement of biome distribution

Such events can overwhelm our response strategies

Additional millions at risk for increases in global temperature

Source: Millions at Risk, M L Parry and M Livermore, University of East Anglia
CO₂ concentration, temperature, and sea level continue to rise long after emissions are reduced.

**Magnitude of response**

- CO₂ emissions peak 0 to 100 years

**Time taken to reach equilibrium**

- Sea-level rise due to ice melting: several millennia
- Sea-level rise due to thermal expansion: centuries to millennia
- Temperature stabilization: a few centuries
- CO₂ stabilization: 100 to 300 years

Impact of stabilizing emissions versus stabilizing concentrations of CO₂

Source: IPCC TAR
Adaptation

Planned anticipatory adaptation has the potential to reduce vulnerability and realize opportunities associated with climate change.

Source: IPCC TAR
Exploiting the Synergies

- Effective mitigation policies would also further other sustainable development goals (economic, equity, environmental)
  - Maximizing co-benefits of the mitigation strategy
  - Implementing no regret options

- The key linkages between mitigation and development are many - macroeconomic impacts, employment creation, inflation, trade
Where do we go from here?

- Develop framework and boundaries for decision making
- Answer the question “Dangerous for whom?”
- Define what is expected from science
- Lodge science rationally in the decision framework
- Create “value” for value judgement
